Open the Autocad.dwg file and apply keygen from that.dwg file. INTRODUCTION ===== A significant number of human body's body organs are arranged in a complex manner. In this arrangement, anatomic organs must have the essential abilities to adapt their functions to other organs so that all organs maintain their functions. The placenta must respond to the needs of the fetus and to the presence of the mother. Therefore, it is not difficult to assume that many diseases related to the placenta (toxoplasmosis, toxocariasis, preeclampsia, and preterm labor) may be related to anatomical distortions and functional alterations. As a result, we performed a study to analyze the placental volume and placental 3D shape during normal gestation and determine whether there were differences in the placental volume and placental shape between normal and pathological gestations. In this study, we also analyzed the correlation between the placental volume and the placental shape and determined whether placental volume and placental shape have any correlation with gestational age. MATERIALS AND METHODS ===== We studied 23 patients with normal gestation (12 first trimester and 11 third trimester) and 24 patients with placenta previa (11 first trimester and 13 third trimester) from our hospital's perinatology service (Figure [1](#F1){ref-type="fig"}). Exclusion criteria were as follows: patients with pregnancy induced hypertension, gestational diabetes, placenta previa with additional medical problems such as a history of liver disease, diabetes mellitus, nephropathy, and active disease. Additionally, patients who were not able to have magnetic resonance (MR) images taken due to a pacemaker or a body implant, as well as patients with fetal anomalies, were excluded. Fetal anatomy was evaluated using a MR compatible 3D-array surface coil scanner (Toshiba MRI, Japan) with the patient in the supine position. All MR scans were performed using the same protocol. The field of view was 14cm × 14cm and the acquisition time was 6 minutes. The total MR imaging volume was acquired using a 3D fast-field-echo (FFE) pulse sequence. No intravenous gadolinium contrast agent was administered. T1-weighted FFE images were acquired in the axial and sagittal planes at a thickness of 0.6mm
